

One screen for every camera in Gujarat.

Without asking twenty-six departments to replace what they already have.

THE PROBLEM

Gujarat is building 80,000 cameras.

Nobody can see them all at once.

26

departments, each with its own system

80,000

cameras, analog and digital, many vendors

1,000 km

between the furthest sites

WHY IT IS HARD

Every department bought a different system.

Different vendors. Different formats. Different rules about who may look. None of them were built to talk to each other, and none of them were wrong to be built that way.

THE OBVIOUS ANSWER

**We could ask all twenty-six
to switch to one system.**

That takes three years, costs a great deal, and helps nobody on the first day.

So we did not.

THE CHOICE

The brief offered four designs. We used three.

MODEL 1

A map of every camera

The foundation. Useful on day one with no analysis at all.

MODEL 3

A translator per vendor

How the systems join without any of them changing.

MODEL 2

One screen

What an officer actually uses. It talks to us, never to the vendors.

MODEL 4

One giant video system

Refused. It means moving every camera's picture to one building.

**Do not move the video.
Move what the video saw.**

HOW IT WORKS

Three steps, and only one of them is new.

ONE

The camera stays

Where it is, owned by whoever owns it, recording to their own system.

TWO

A computer watches

Placed beside the camera. It sees the picture and writes down what is in it.

THREE

Only the note travels

The picture never leaves the building. The sentence describing it does.

WHAT ACTUALLY TRAVELS

A sentence, not a picture.

SENDING THE VIDEO

2 Mbps

Every second, from every camera, for ever. Multiplied by eighty thousand, it is a network nobody is going to build.

SENDING WHAT IT SAW

400 bytes

motorcycle · camera 12 · 21:14 · GJ 05

That is the whole message. It is five thousand times smaller than the picture it came from.

JOINING

A department joins by filling in one form.

We taught our software to speak each vendor's format, so nobody has to learn ours. Adding the twenty-sixth department changes nothing about how the first one works.

A department with no modern equipment at all can still be on the map on the day it sends us a spreadsheet.

We read the vehicle, not the frame.

Most systems photograph a plate once and hope. We follow the same vehicle across every frame it appears in, read the plate in each one, and take the answer they agree on.

One frame is a guess.

Twelve frames agreeing is a reading.

FINDING A VEHICLE

Put a plate on the list.

The moment any camera in the state sees it, an officer knows. Not on the next search, not in the morning report. At the moment of the reading.

THE ALERT

Where and when

Which camera, what time, and how sure the reading was. A near match is shown as a near match, never hidden to keep the screen tidy.

THE ROUTE

Where it went

Every sighting in time order on a map. A leg that would need 200 km/h is flagged as doubtful rather than quietly removed.

Knowing a camera exists is not sensitive. Seeing what it sees is a decision.

So we separated them. Every camera in the state is on the map for everyone. Watching one you do not own means asking the unit that does, and someone there saying yes.

That permission is personal, expires on its own, can be withdrawn mid-stream, and is written down either way. Refusals are recorded as carefully as approvals.

WHY THIS SCALES

The same state network, two very different asks.

IF YOU MOVE THE VIDEO

160 Gbps

Sustained, plus 1.7 petabytes of footage every day, and every camera password sitting in one building.

IF YOU MOVE THE MEANING

1 Gbps

Statewide. Departments keep their own footage, and no central system holds a key to anybody's camera.

RUNNING TODAY, ON FIFTY LIVE FEEDS

Not a prototype. A system with numbers.

50/50

cameras in service,
all live on one wall

36/48

plates a person can read, read
right, on 38 recorded clips

0

false plates confirmed or sent,
day or night

332

automated tests passing

Measured to 20 September 2026, on one laptop. Grid CAM06 at noon: 15 of the 16 legible plates, none wrong.
278,362 vehicles and objects detected across 30 grid cameras, our Delhi test clip and 19 public TfL cameras.

THE HONEST PART

Most of these cameras cannot read a plate.

They were mounted to watch a junction, not to read a number. On a wide view a plate is thirty pixels across, and nothing can read that. Not our software, not anyone's.

**That is the lens, not the code.
We would rather say so than invent a number.**

GETTING THERE

Every step is worth having on its own.

PHASE 1

50 cameras

One district. Proves the whole chain on real feeds. This is where we are.

PHASE 2

2,000 cameras

Three districts, two departments, genuinely different vendors.

PHASE 3

15,000 cameras

Every district, one department. Statewide load, failover tested.

PHASE 4

80,000 cameras

All twenty-six departments. Steady state.

An accurate map of every camera in Gujarat is useful on the day it exists, before a single piece of analysis runs. Nobody has one today.

THE LIVE WALL

Fifty cameras, one screen.

Live wall, 14 September 2026. TfL JamCam feeds: Powered by TfL Open Data.

LIVE

Every tile is the feed

Each tile is the camera's live picture with the edge's vehicle detection drawn on it.

THREE SOURCES

One wall

30 government grid cameras, our Delhi test clip and 19 public London traffic cameras.

READING PLATES, LIVE

The plate, read on the live feed.

Our Delhi test clip

Every vehicle boxed; the green box is the plate our ANPR read.

Grid CAM06, Madhuram Bypass Road

Each read carries its confidence, and a low one is shown as low.

WATCHLIST TO ALERT

From a read to an alert, in seconds.

MATCHED AT INGEST

Known when it is read

A plate goes up with the frame that settles it and is matched, exact or near, as it arrives.

THE TEST CASE

Continuous readers

Cameras with legible plates are watched all the time, so a designated vehicle is seen, then traced.

PRIORITISED

Critical, high, review

Exact stolen or wanted leads the console; a near match is looked at before anyone is sent.

BEYOND PLATES

Intrusion zones

A restricted zone per camera, beside wrong-way, stopped-in-lane and person-in-traffic.

LEAVES THE SCREEN

Signed webhook out

Dispatch, SMS or messaging sit behind it; raise, acknowledge and dismiss are audited.

HONEST

No guessed plates

A plate too small to read is refused, which is why an alert from this system can be acted on.

This is what one laptop could do.

One laptop watches all fifty feeds live and reads plates on two of them.
Given the hardware a state deploys, the same software reads every
camera, continuously.
